## **Python Programming Fundamentals Cheat Sheet**

Package/Method Description	Syntax and Code Example
Returns 'True' if both statement1 and statement2 are 'True' Otherwise, returns 'False'.	Syntax: statement1 and statement2  Example:

about:blank 1/23

		Syntax:
Class Definition	Defines a blueprint for creating objects and defining their attributes and behaviors.	<pre>Example:     class Person:         definit(self, name, age):             self.name = name             self.age = age</pre>
Define Function	A `function` is a reusable block of code that performs a specific task or set of tasks when called.	<pre>Syntax:    def function_name(parameters): # Function body</pre>

about:blank 2/23

		<pre>Example:    def greet(name): print("Hello,", name)</pre>
Equal(==)	Checks if two values are equal.	Syntax:  variable1 == variable2  Example 1:  5 == 5

O/	1/25, 1.17 1 101		about.blank
			returns True Example 2:  age = 25 age == 30
	For Loop	A 'for' loop repeatedly executes a block of code for a specified number of iterations or over a sequence of elements (list, range, string, etc.).	Syntax:  for variable in sequence: # Code to repeat

		Example 1:
		for num in range(1, 10): print(num)
		Example 2:
		<pre>fruits = ["apple", "banana", "orange", "grape", "kiwi"] for fruit in fruits:     print(fruit)</pre>
Function Call	A function call is the act of executing the code within the function using the provided arguments.	Syntax: function_name(arguments)

		<pre>Example:     greet("Alice")</pre>
Greater Than or Equal To(>=)	Checks if the value of variable 1 is greater than or equal to variable 2.	<pre>Syntax:     variable1 &gt;= variable2  Example 1:     5 &gt;= 5 and 9 &gt;= 5</pre>

		returns True  Example 2:  quantity = 105 minimum = 100 quantity >= minimum
		returns True
Greater Than(>)	Checks if the value of variable1 is greater than variable2.	Syntax:  variable1 > variable2

	Example 1: 9 > 6
	returns True
	Example 2:
	age = 20 max_age = 25 age > max_age
	returns False
Executes code block 'if' the condition is 'True'.	Syntax:
	if condition: #code block for if statement
	Example:
	Executes code block `if` the condition is `True`.

```
if temperature > 30:
                                                                               print("It's a hot day!")
If-Elif-Else
                    Executes the first code block if condition 1 is 'True',
                                                                       Syntax:
                    otherwise checks condition2, and so on. If no condition is
                                                                           if condition1:
                    'True', the else block is executed.
                                                                           # Code if condition1 is True
                                                                           elif condition2:
                                                                           # Code if condition2 is True
                                                                           else:
                                                                           # Code if no condition is True
                                                                       Example:
                                                                           score = 85 # Example score
                                                                           if score >= 90:
                                                                               print("You got an A!")
                                                                           elif score >= 80:
                                                                               print("You got a B.")
                                                                           else:
```

		<pre>print("You need to work harder.") # Output = You got a B.</pre>
If-Else Statement	Executes the first code block if the condition is 'True', otherwise the second block.	Syntax:  if condition: # Code, if condition is True else: # Code, if condition is False
		<pre>Example:     if age &gt;= 18:         print("You're an adult.")     else:         print("You're not an adult yet.")</pre>

7/25, 7.17 1 W		about.blank
Less Than or Equal	Checks if the value of variable 1 is less than or equal to	Syntax:
To(<=)	variable2.	variable1 <= variable2
		Example 1:
		5 <= 5 and 3 <= 5
		returns True
		Example 2:
		<pre>size = 38 max_size = 40 size &lt;= max_size</pre>

77720, 7.17 T W		assausiani
		returns True
Less Than(<)	Checks if the value of variable1 is less than variable2.	Syntax:
		variable1 < variable2
		Example 1:
		4 < 6
1		

		returns True  Example 2:  score = 60 passing_score = 65 score < passing_score  returns True
Loop Controls	'break' exits the loop prematurely. 'continue' skips the rest of the current iteration and moves to the next iteration.	<pre>Syntax:     for: # Code to repeat         if # boolean statement             break     for: # Code to repeat         if # boolean statement             continue</pre>

		<pre>Example 1:     for num in range(1, 6):         if num == 3:             break         print(num)</pre>
		<pre>for num in range(1, 6):     if num == 3:         continue     print(num)</pre>
NOT	Returns `True` if variable is `False`, and vice versa.	Syntax: not variable

about:blank 14/23

		Example:  isLocked = False print(not isLocked)  returns True if the variable is False (i.e., unlocked).
Not Equal(!=)	Checks if two values are not equal.	Syntax:
		variable1 != variable2

77725, 7.17 1 W		about.biain
		Example:
		a = 10 b = 20 a != b
		returns True
		Example 2:
		count=0 count != 0
Object Creation	Creates an instance of a class (chieat) using the class	returns False Syntax:
Object Creation	Creates an instance of a class (object) using the class constructor.	<pre>Syntax:     object_name = ClassName(arguments)</pre>

-, .	720, 7.17 1 101		about.blaim
			Example:  person1 = Person("Alice", 25)
	OR	are 'True'. Otherwise, returns 'False'.	Syntax:  statement1 or statement2  Example:

		"Farewell Party Invitation"  Grade = 12 grade == 11 or grade == 12
		returns True
range()	Generates a sequence of numbers within a specified range.	<pre>range(stop) range(start, stop) range(start, stop, step)</pre>
		Example:  range(5) #generates a sequence of integers from 0 to 4.  range(2, 10) #generates a sequence of integers from 2 to 9.  range(1, 11, 2) #generates odd integers from 1 to 9.

,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,,		about.blank
		Syntax:
		return value
Return Statement	'Return' is a keyword used to send a value back from a function to its caller.	<pre>Example:    def add(a, b): return a + b    result = add(3, 5)</pre>
Try-Except Block	Tries to execute the code in the try block. If an exception of the specified type occurs, the code in the except block is	Syntax:  try: # Code that might raise an exception except

	executed.	ExceptionType: # Code to handle the exception
		<pre>Example:     try:         num = int(input("Enter a number: "))     except ValueError:         print("Invalid input. Please enter a valid number.")</pre>
Try-Except with Else Block	Code in the 'else' block is executed if no exception occurs in the try block.	Syntax:  try: # Code that might raise an exception except ExceptionType: # Code to handle the exception else: # Code to execute if no exception occurs

		<pre>Example:     try:         num = int(input("Enter a number: "))     except ValueError:         print("Invalid input. Please enter a valid number")     else:         print("You entered:", num)</pre>
Try-Except with Finally Block	Code in the `finally` block always executes, regardless of whether an exception occurred.	Syntax:  try: # Code that might raise an exception except ExceptionType: # Code to handle the exception finally: # Code that always executes

about:blank

21/23

		<pre>try:     file = open("data.txt", "r")     data = file.read() except FileNotFoundError:     print("File not found.") finally:     file.close()</pre>
While Loop	A 'while' loop repeatedly executes a block of code as long as a specified condition remains 'True'.	Syntax: while condition: # Code to repeat
		<pre>Example:     count = 0     while count &lt; 5:         print(count)         count += 1</pre>
